Project Report: Validation System Using Finite Automata (Password, URL, Email, and Phone Validator)

Design and Implementation of Finite Automata Based Validation System

Muhammad Umair

Roll No: 66144

Course: Theory of Automata

Instructor: Miss Misbah Anwer

Abstract

This report present the developement of a validation system using Deterministic Finite Automata (DFA) principals. The system check inputs such as passwords, URLs, email address, and phone numbers. The approach demonstrates how automata theory can be applied to practical problem in software developement. The report include background, related work, methodology, experimental result, conclusion, and refrences.

1.1 Introduction

1.1.1 Background

Finite Automata is foundational model in theoretical computer science used for pattern recognition and language parsing. They form the basic of regular languages and is widely taught in Theory of Automata courses. A DFA process a sequence of input symbol and determine whether the input belong to a defined language.

1.1.2 Motivation

With the increasing need for secure and correct data validation in software system, automata models offers a systematic and determinstic method for validating structured strings. For example, ensuring strong password and valid URLs improve system security and user experience.

1.1.3 Significance

By building practical validator using DFA, this project bridge theoretical concept with real world applications. The system is design to be both educational and usefull in real software scenario and learning purpose.

1.2 Related Work

Several studies has explored automated validation techniques using formal languages and pattern recognition:

Fandino-Mesa et al. describe the use of regular grammer to validate email address, showing how formal language theory applys directly to input validation problem in software systems. They build and tests finite automata for email syntax based on recommended standards [1].

Password strength reserach highlight the need for robust validation system. Studies on password complexity emphasise factor such as character diversity and lenght as determinant of strength [2].

Studies on machine learning model for password strength reveals alternative approach like Markov models and neural network for estimating password security, illustrating the broader context of validation beyond simple rule based system [3].

Further work on regex analysis underscrores potential vulnerabilities in pattern matching system and the importance of effient pattern validation method [4].

Research on formal grammer analysis also demonstrates the value of regular expressions and grammer in syntactic validation task such as email parsing and lexical analysis process [5].

1.3 Methodology

The project implement four validator using DFA-like logic and structure:

1.3.1 Password Strength Checker

A DFA track whether uppercase, lowercase, numeric, and symbolic character have been seen or not. The input is accept only when all condition is met correctly.

1.3.2 URL Validator

The URL DFA process protocol, domain, top-level domain (TLD), and optional path. It transit systematically through protocol recognition and domain structure rule.

1.3.3 Email Validator

The email DFA check the presence of a username, an '@' symbol, a domain, and a valid extention. The transition ensure correct sequencing of this component.

1.3.4 Phone Number Validator

This DFA check phone number format such as international and local standard, ensuring correct prefix and digit count.

Each validator read input character by character and update state accordingly, following determinstic transition function.

1.4 Results & Experiments

The system was test using a range of valid and invalid example for evaluation:

1.4.1 Password Strength Validator

Implementation Code

The following code implements a DFA-based password strength checker that ensures the presence of uppercase, lowercase, numeric, and special characters.

```
def validate_password(password):  
    has_upper = False  
    has_lower = False  
    has_digit = False  
    has_symbol = False  
  
    for ch in password:  
        if ch.isupper():  
            has_upper = True
```

```

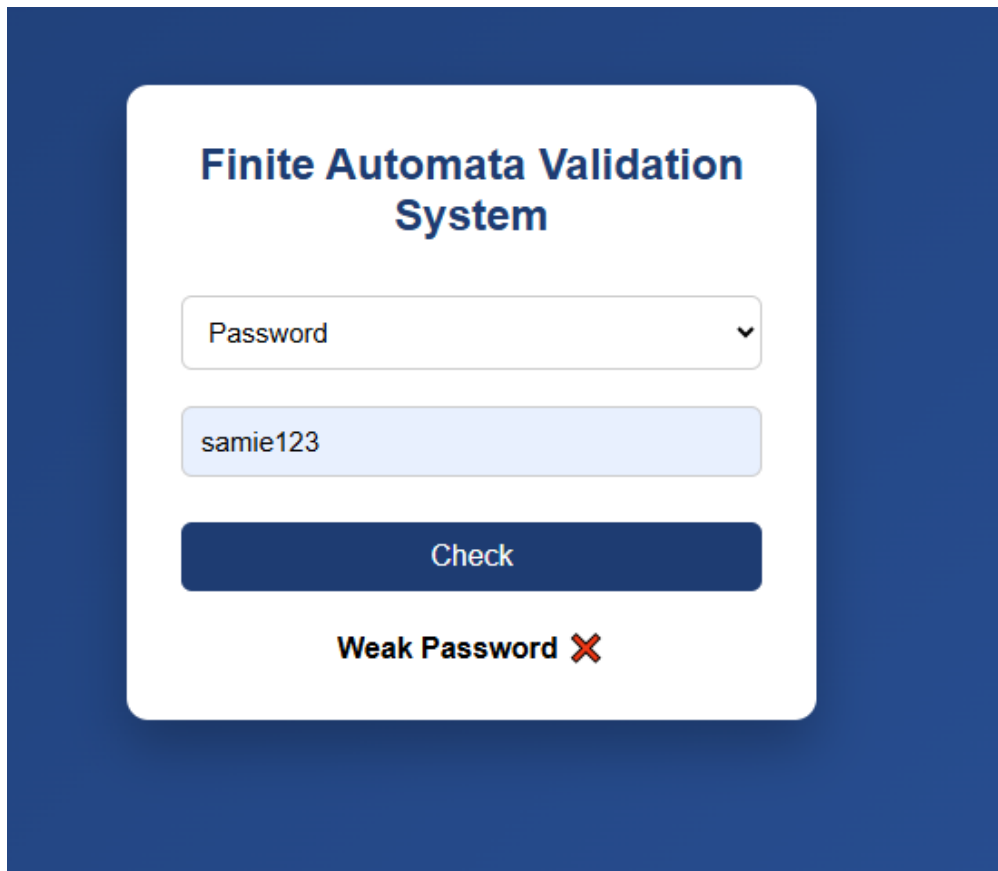

elif ch.islower():
    has_lower = True
elif ch.isdigit():
    has_digit = True
else:
    has_symbol = True

return has_upper and has_lower and has_digit and has_symbol

```

Listing 1.1: Password Strength Validator Code

Experimental Output

The image shows a web application titled "Finite Automata Validation System". It features a dropdown menu labeled "Password" with a downward arrow. Below the dropdown is a text input field containing the password "samie123". A dark blue button labeled "Check" is positioned below the input field. At the bottom of the interface, the text "Weak Password" is displayed in bold, followed by a red "X" icon, indicating that the password is not strong enough.

Figure 1.1: Password Validation Result

1.4.2 URL Validator

Implementation Code

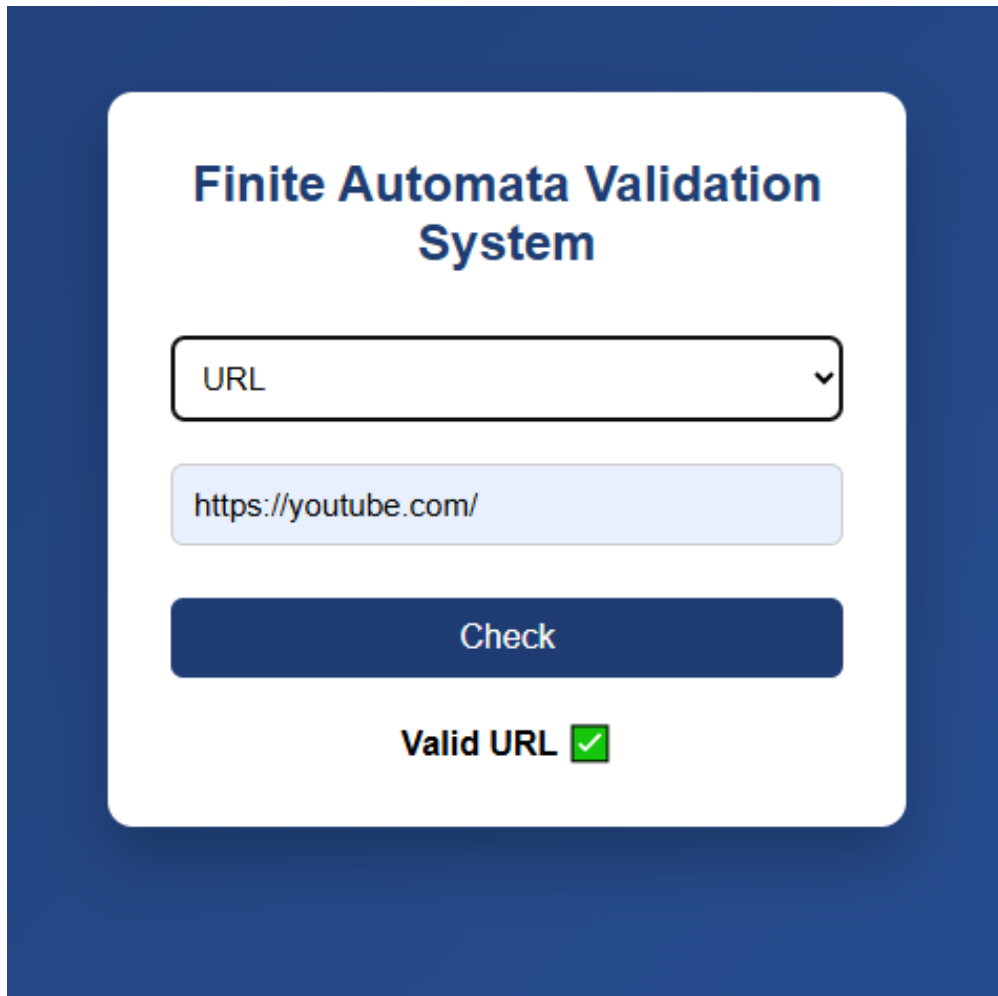

This validator checks whether the given URL follows a valid protocol and domain structure.

```
import re
```

```
def validate_url(url):  
    pattern = r"^(https?:\/\/)?(www\.)?[a-zA-Z0-9\-\_]+\.[a-zA-Z]{2,}$"  
    "  
    return re.match(pattern, url) is not None
```

Listing 1.2: URL Validator Code

Experimental Output

The image shows a web interface for a "Finite Automata Validation System". It features a dark blue background with a white rounded rectangle in the center. Inside the rectangle, the title "Finite Automata Validation System" is displayed in bold blue text. Below the title is a dropdown menu with "URL" selected and a downward arrow. Underneath the dropdown is a light blue input field containing the text "https://youtube.com/". Below the input field is a dark blue button with the text "Check" in white. At the bottom of the white rectangle, the text "Valid URL" is shown in bold black, followed by a green checkmark icon.

Figure 1.2: URL Validation Result

1.4.3 Email Validator

Implementation Code

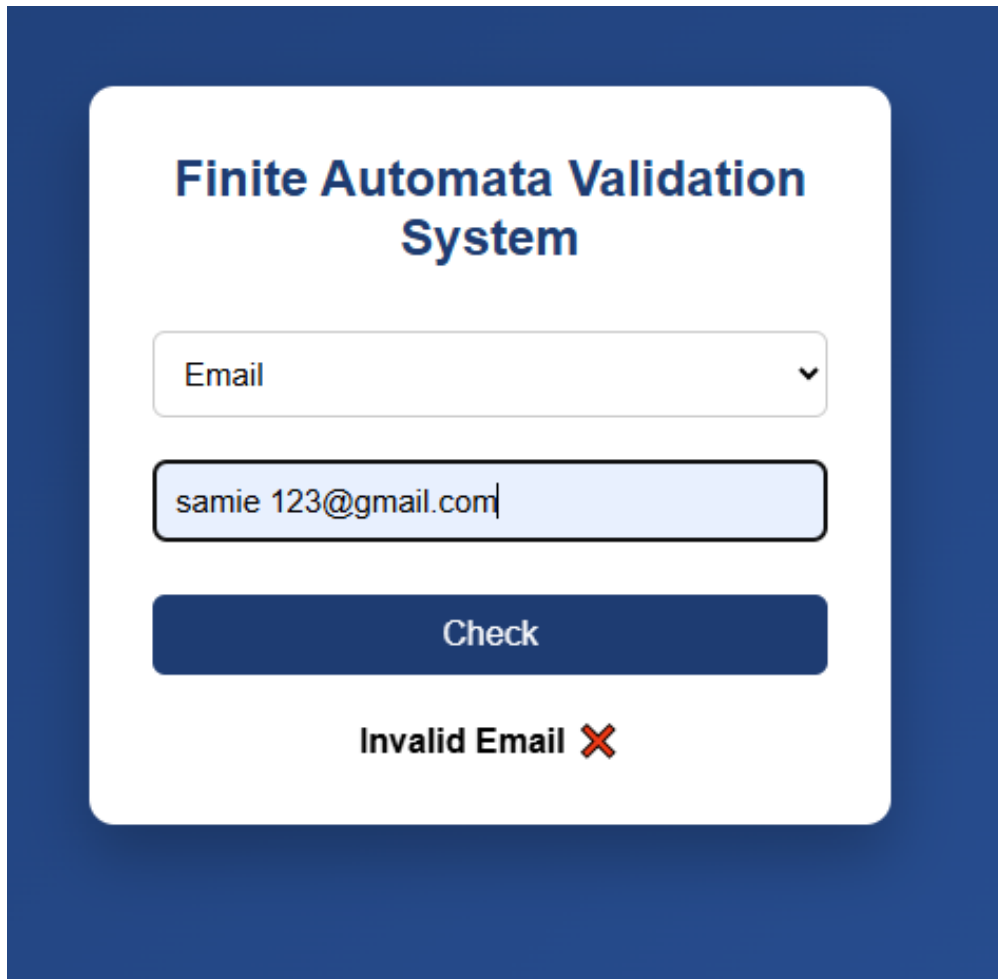

The email validator ensures the correct sequence of username, '@' symbol, domain name, and extension.

```
import re

def validate_email(email):
    pattern = r"^[a-zA-Z0-9._]+@[a-zA-Z]+\.[a-zA-Z]{2,}$"
    return re.match(pattern, email) is not None
```

Listing 1.3: Email Validator Code

Experimental Output

The screenshot shows a web interface titled "Finite Automata Validation System". It features a dropdown menu labeled "Email" with a downward arrow. Below the dropdown is a text input field containing the email address "samie 123@gmail.com". Underneath the input field is a dark blue button labeled "Check". At the bottom of the interface, the text "Invalid Email" is displayed in bold, followed by a red "X" icon, indicating that the provided email address is not valid according to the system's criteria.

Figure 1.3: Email Validation Result

1.4.4 Phone Number Validator

Implementation Code

This validator checks phone numbers for valid prefixes and correct digit length.

```
def validate_phone(phone):  
    if phone.startswith("+92") and len(phone) == 13:  
        return True  
    elif phone.startswith("03") and len(phone) == 11:  
        return True  
    return False
```

Listing 1.4: Phone Number Validator Code

Experimental Output

The image shows a web application interface titled "Finite Automata Validation System". It features a dropdown menu labeled "Phone" with a downward arrow. Below the dropdown is a text input field containing the phone number "+923182243672". A dark blue button labeled "Check" is positioned below the input field. At the bottom, the text "Valid Phone Number" is displayed next to a green checkmark icon, indicating a successful validation.

Figure 1.4: Phone Number Validation Result

1.4.5 Summary of Results

The validator consistently accepted valid input and rejected incorrect format, demonstrating the effectiveness of DFA-based logic system.

1.5 Conclusion

This project demonstrates how deterministic finite automata can be used to validate structured string pattern. The approach model real world input validation problem within a formal theoretical framework. The result confirm that DFA principals can provide reliable and determinstic outcome for common validation task.
